FACULTY INVESTIGATORS:

S. A. SCHAAF, PROFESSOR OF ENGINEERING SCIENCES
L. TALBOT, ASSOCIATE PROFESSOR OF AERONAUTICAL SCIENCES
G. J. MASLACH, PROFESSOR OF AERONAUTICAL ENGINEERING

I. INTRODUCTION

Previous measurements of drag forces acting on cylinders normal to a rarefied gas flow¹ have been concentrated in the transition and near free molecule flow range of Knudsen number where direct comparison with existing theories could be made. Following the completion of that work it appeared desirable to extend the data to near continuum flow conditions. In addition, the analysis of previous data by normalization techniques² indicated a need to repeat certain tests in an attempt to reduce experimental scatter. It is the purpose of this report to present all results obtained to date, including previous work and new measurements involving three additional models, with a complete listing of all data which may be of value to those contemplating future theoretical work in this field.

II. EXPERIMENTAL METHOD

A. Experimental Equipment

All tests were performed with the equipment previously described.¹ The three new models were solid steel rods; 0.0265 inch diameter, 0.0500 inch diameter and 0.1103 inch diameter. These supplemented the former models, 0.0003 inch, 0.0009 inch, 0.0015 inch, 0.0033 inch and 0.010 inch diameter. The same adjustable length cylindrical shields were used to fix the length of model exposed to the stream. The slotted caps terminating the shields were rebored to provide a close fit for each new model. Thus the ratio of shield diameter to model diameter varied with each model. No additional model temperatures were obtained with the new larger models.

B. Experimental Procedures

All procedures and flow control methods previously described were continued for the tests involving the three larger models. The length of exposed model varied from approximately three quarters of an inch to approximately two inches. Data obtained during a given run were immediately reduced to permit a plot of aerodynamic force versus model length. This control curve was thus available before changes were made in the experimental setup. The linearity of this plot and the extrapolation of the force data for a zero length model were constantly checked. As before, small positive force intercepts were noted for the theoretical zero length model for most of the runs.

III. DATA REDUCTION AND ERROR ANALYSIS

Standard methods of data reduction were employed to determine the free stream flow properties and the aerodynamic forces acting on the model. For the larger models the uncertainty in the quantity C_x was reduced due to the greater precision possible in the measurement of the model diameters. The larger forces, in the gram range, resulted in sizable spring extension and thus a reduction of this error source. The total of all error contributions in the determination of C_x for the three new models in all flow conditions varied from 1.5 to 2.0%.

It is interesting to note that the noticeable scatter in the original Mach 4 results using a 0.0033 inch nominal diameter model was traced to a change in model diameter in the course of the tests. The model, a butt welded thermocouple, was broken, repaired and remounted. In the refabrication the thermocouple joint in the center of the model length was

hand polished, resulting in a reduction in diameter of approximately 10%. New tests were run with this new cylinder and included in the final results for all models. These results are presented in Figures 1, 2 and 3 with a normalized presentation in Figure 4.

IV. RESULTS

The experimental results indicate a smooth transition from continuum drag coefficient values to predicted free molecular flow drag coefficients. Normalization of the measured drag values reveals a marked Mach number dependency. Future experimental programs are indicated, including extension to higher and lower Mach numbers, and a detailed pressure survey of the entire cylinder surface.
